#### Data Types, Variables, and Operators in C

Md. Aminul Islam Shazid

#### **Outline**

- 1 Data Types and Variables
- 2 Operators
- 3 Input, Output (IO)
- 4 Exercise

# Data Types and Variables

#### **Basic Data Types in C**

- **int**: whole numbers (typically 4 bytes). *Usage:* integer data, counters, loop indices.
- **float**: single-precision decimals (~6 digits). *Usage:* decimal data.
- **double**: double-precision decimals (~15 digits). *Usage*: precise calculations, finance.
- **char**: single character (1 byte, ASCII). *Usage:* characters, text handling.
- void: represents no value.
   Usage: function return type, pointers.
- **short, long, unsigned**: integer variants. *Usage:* memory optimization, large values.

#### Variable Sizes and Precision

- Sizes vary by system/compiler, but common values:
  - char: 1 byteshort: 2 bytes
  - int: 4 bytes
  - long: 4 or 8 bytes
  - float: 4 bytes (about 6 decimal digits)
  - double: 8 bytes (about 15 decimal digits)
- Use sizeof() operator to check actual size.
- Precision: float (single) vs. double (double precision).

#### Variable Definition and Declaration

- Syntax: data\_type variable\_name;
- Initialization: int x = 10;
- Can also do: int x; x = 10;
- Scope:
  - · Local: inside a function.
  - Global: outside all functions.
- Constants:
  - o const int MAX = 100;
  - #define PI 3.14

#### Type Casting in C

- Type casting converts a variable from one data type to another
- Implicit casting (type promotion):
  - Done automatically by the compiler.
  - Example: int x = 5; double y = x; (x promoted to double)
- Explicit casting:
  - Done by the programmer using cast operator.
  - Syntax: (type) expression
  - Example: double a = 5.7; int b = (int)a; (b = 5)
- Use casting carefully: may cause data loss (e.g., truncation).

#### Variable Naming Rules in C

- Must begin with a letter or underscore (\_).
- Can contain letters, digits, and underscores.
- Case-sensitive: value and Value are different.
- Cannot be a reserved keyword (int, return, etc.).
- Should be meaningful for readability (e.g., total, not x1).

### Operators

#### Operators in C

- Arithmetic: +, -, \*, /, %
   Perform basic mathematical operations.
- Relational: <, <=, >, >=, ==, !=
   Compare two values, result is either true (1) or false (0).
- Logical: &&, ||, !
   Combine conditions: && (AND), || (OR), ! (NOT).
- Assignment: =, +=, -=, \*=, /= Store values in variables or update them with shorthand forms.

#### **Prefix vs Postfix Operators**

- Increment / Decrement operators: ++, --
- Prefix form (++x, --x)
  - Variable is updated first, then used in the expression.
  - Example:

```
• int x = 5;
• int y = ++x; ()x=6, y=6)
```

- Postfix form (x++, x−−)
  - Variable is used first, then updated.
  - · Example:

```
int x = 5;int y = x++; (x=6, y=5)
```

 Rule of thumb: prefix = "increment before use", postfix = "increment after use".

#### **Truth Tables for Logical Operators**

#### **AND (&&)**

А	В	A && B
0	0	0
0	1	0
1	0	0
1	1	1

#### OR (||)

Α	В	$A \parallel B$
0	0	0
0	1	1
1	0	1
1	1	1

#### **NOT (!)**

Α	!Α
0	1
1	0

#### **Order of Evaluation and Precedence**

Operators in C follow a precedence hierarchy.

#### Examples (highest to lowest):

- (): Parentheses
- \*, /, %: Multiplication, Division, Modulus
- +, -: Addition, Subtraction
- <, >, <=, >=: Relational
- ==, !=: Equality
- &&: Logical AND
- ||: Logical OR
- =: Assignment (lowest)

Use parentheses () to make evaluation explicit.

Example: int x = 2 + 3 \* 4;  $\rightarrow$  result is 14, not 20.

Input, Output (IO)

#### Formatted Output: printf()

- Used to display output to the screen.
- General form: printf("format string", values);
- Format specifiers:
  - ∘ %d → integer
  - %f → float/double
  - %c → char
  - ∘ %s → string
- Example: printf("Sum = %d", x);

#### Formatted Input: scanf()

- Used to take input from the user.
- General form: scanf("format string", &variables);
- Format specifiers are the same as for printf.
- Example: scanf("%d", &x);

#### Why use & in scanf()?

- scanf() needs the address of a variable to store the input value.
- The operator & ("address-of") provides that memory location.
- Example:
  - int x;
  - o scanf("%d", &x);
  - Without &, the program will not know where to put the value.
- Exception: For strings (%s), the variable itself is already an address, so no & is needed.

## Exercise

#### **Exercise**

- Write a C program that demonstrates the basic arithmetic operations.
- Write a C program that divides an 5 (integer) by 2 (integer), 5.0 (float) by 2 (integer), and 5 (integer) by 2.0 (float).
- Write a C program that demonstrates the use of the modulo (%) operator.
- Predict the output:

```
int x = 5; printf("%d", x++);
int y = 5; printf("%d", ++y);
```

#### **Questions?**
