Data Types, Variables, and Operators in C

Md. Aminul Islam Shazid

Outline

- 1 Data Types and Variables
- 2 Operators
- 3 Input, Output (IO)
- 4 Examples
- **5** Exercise

Data Types and Variables

Basic Data Types in C

- int: whole numbers (typically 4 bytes)
 Usage: integer data, counters, loop indices
- float: single-precision decimals (~6 digits)
 Usage: decimal data
- **double**: double-precision decimals (~15 digits) *Usage:* precise calculations, finance
- char: single character (1 byte, ASCII)
 Usage: characters, text handling
- void: represents no value Usage: function return type, pointers
- **short, long, unsigned**: integer variants *Usage:* memory optimization, large values

Variable Sizes and Precision

• Sizes vary by system/compiler, but common values:

char: 1 byteshort: 2 bytesint: 4 bytes

■ long: 4 or 8 bytes

float: 4 bytes (about 6 decimal digits)double: 8 bytes (about 15 decimal digits)

• Use sizeof() operator to check actual size

Precision: float (single) vs. double (double precision)

Variable Definition and Declaration

- Syntax: data_type variable_name;
- Initialization: int x = 10;
- Can also do: int x; x = 10;
- Scope:
 - Local: inside a function
 - Global: outside all functions
- Constants:
 - const int MAX = 100;
 - #define PI 3.14

Type Casting in C

- Type casting converts a variable from one data type to another
- Implicit casting (type promotion):
 - Done automatically by the compiler
 - Example: int x = 5; double y = x; (x promoted to double)
- Explicit casting:
 - Done by the programmer using cast operator
 - Syntax: (type) expression
 - Example: double a = 5.7; int b = (int)a; (b = 5)
- Use casting carefully: may cause data loss (e.g., truncation)

Variable Naming Rules in C

- Must begin with a letter or underscore (_)
- Can contain letters, digits, and underscores
- Case-sensitive: value and Value are different
- Cannot be a reserved keyword (int, return, etc.)
- Should be meaningful for readability (e.g., total, not x1)

Operators

Operators in C

- Arithmetic: +, -, *, /, %
 Perform basic mathematical operations
- Relational: <, <=, >, >=, ==, !=
 Compare two values, result is either true (1) or false (0)
- Logical: &&, ||, !
 Combine conditions: && (AND), || (OR), ! (NOT)
- Assignment: =, +=, -=, *=, /=
 Store values in variables or update them with shorthand forms

Prefix vs Postfix Operators

- Increment / Decrement operators: ++, --
- Prefix form (++x, --x)
 - Variable is updated first, then used in the expression
 - Example:

- Postfix form (x++, x--)
 - Variable is used first, then updated
 - Example:

```
▶ int x = 5;
▶ int y = x++;
(x=6, y=5)
```

• Rule of thumb: prefix: "increment before use", postfix: "increment after use".

Truth Tables for Logical Operators

AND (&&)

А	В	A && B
0	0	0
0	1	0
1	0	0
1	1	1

OR (||)

Α	В	$A \parallel B$	
0	0	0	
0	1	1	
1	0	1	
1	1	1	

NOT (!)

Α	!A
0	1
1	0

Order of Evaluation and Precedence

Operators in C follow a precedence hierarchy.

Examples (highest to lowest):

- (): Parentheses
- *, /, %: Multiplication, Division, Modulo
- +, -: Addition, Subtraction
- <, >, <=, >=: Relational
- ==, !=: Equality
- &&: Logical AND
- ||: Logical OR
- =: Assignment (lowest)

Use parentheses () to make evaluation explicit.

Example: int x = 2 + 3 * 4; \rightarrow result is 14, not 20.

Input, Output (IO)

Formatted Output: printf()

- Used to display output to the screen
- General form: printf("format string", values);
- Format specifiers:
 - %d → integer
 - %f → float/double
 - %c → char
 - %s → string
- Example: printf("Sum = %d", x);

Formatted Input: scanf()

- Used to take input from the user
- General form: scanf("format string", &variables);
- Format specifiers are the same as for printf
- Example: scanf("%d", &x);

Why use the ampersand sign (&) in scanf()?

- scanf() needs the address of a variable to store the input value
- The operator & ("address-of") provides that memory location
- Example:
 - int x;
 - scanf("%d", &x);
 - Without &, the program will not know where to put the value
- Exception: For strings (%s), the variable itself already holds an address, so no & is needed

Examples

Sum of Two Integers

```
#include <stdio.h>
2
   int main(){
       int a, b, c;
    a = 1;
       b = 2;
      c = a + b;
       printf("%d", c);
       return 0;
10
11
```

Sum of Two User-Given Integers

```
#include <stdio.h>
 2
   int main(){
 3
        int a, b;
        printf("Enter first integer:\n"); // \n: newline
 5
 6
        scanf("%d", &a);
 8
        printf("Enter second integer:\n");
        scanf("%d", &b);
10
        int c = a + b;
11
        printf("The sum is: %d", c);
12
        return 0;
13
14
```

Implicit Typecasting

```
#include <stdio.h>
   int main() {
       int i = 10, j;
        float d, e = 5.25;
 4
 5
       // implicit typecasting (int -> float):
        d = i;
        printf("Value of i (int): %d\n", i);
        printf("Value of d (double): %f\n", d);
10
       // implicit typecasting (float -> int):
11
        i = e;
12
        printf("Value of j (int): %d", j);
13
14
        return 0;
15
```

Explicit Typecasting

```
#include <stdio.h>
   int main() {
       double d = 9.78;
       int i:
6
       // explicit typecasting (double -> int)
       i = (int)d:
       printf("Value of d (double): %lf\n", d);
10
        printf("Value of i (int after explicit cast):
11
        - %d\n", i);
12
       return 0;
13
14
```

Exercise

Exercise

- Write a C program that demonstrates the basic arithmetic operations
- Write a C program that divides an 5 (integer) by 2 (integer), 5.0 (float) by 2 (integer), and 5 (integer) by 2.0 (float)
- Guess the outputs:

```
int x = 5; printf("%d", x++);
int y = 5; printf("%d", ++y);
```
